The NASA STI Program...in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

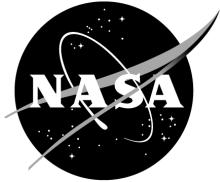

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA's counterpart of peer-reviewed formal professional papers but has less stringent limitations on manuscript length and extent of graphic presentations.
- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or cosponsored by NASA.
- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and mission, often concerned with subjects having substantial public interest.
- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that complement the STI Program Office's diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results...even providing videos.

For more information about the NASA STI Program Office, see the following:

- Access the NASA STI program home page at <<http://www.sti.nasa.gov>>
- E-mail your question via the Internet to <help@sti.nasa.gov>
- Fax your question to the NASA STI Help Desk at 443-757-5803
- Phone the NASA STI Help Desk at 443-757-5802

TABLE OF CONTENTS

1. INTRODUCTION	1
2. RESULTS AND DISCUSSION	3
2.1 Annual Averages of HadSST in the Niño 3.4 Region (1871–2008)	3
2.2 Monthly and 12-mma Values of HadSST in the Niño 3.4 Region (1871–2008)	6
2.3 2-mma Values of Seasonally Adjusted Monthly Means of HadSST (D(m2)) and SOI (SOI(2)) in the Niño 3.4 Region (1871–2008)	27
2.4 The ONI Values in the Niño 3.4 Region (1950–2008)	33
2.5. The Duration-Maximum Anomaly Association for ENSO Extreme Events	34
2.6. Recurrence Periods of the ENSO Extremes	35
2.7 Decadal Aspects of ENSO Extremes	38
3. SUMMARY	40
APPENDIX	43
REFERENCES	81

LIST OF FIGURES

1.	Annual and 10-yma values of (a) mean and (b) high values of HadSST in the Niño 3.4 region from 1871 to 2008	4
2.	Annual and 10-yma values of (a) low values and (b) differences (high minus low) of HadSST in the Niño 3.4 region from 1871 to 2008	5
3.	Annual and 10-yma values of January values of HadSST in the Niño 3.4 region from 1871 to 2009	11
4.	Annual and 10-yma values of February values of HadSST in the Niño 3.4 region from 1871 to 2009	12
5.	Annual and 10-yma values of March values of HadSST in the Niño 3.4 region from 1871 to 2008	13
6.	Annual and 10-yma values of April values of HadSST in the Niño 3.4 region from 1871 to 2008	14
7.	Annual and 10-yma values of May values of HadSST in the Niño 3.4 region from 1871 to 2008	15
8.	Annual and 10-yma values of June values of HadSST in the Niño 3.4 region from 1871 to 2008	16
9.	Annual and 10-yma values of July values of HadSST in the Niño 3.4 region from 1871 to 2008	17
10.	Annual and 10-yma values of August values of HadSST in the Niño 3.4 region from 1871 to 2008	18
11.	Annual and 10-yma values of September values of HadSST in the Niño 3.4 region from 1871 to 2008	19
12.	Annual and 10-yma values of October values of HadSST in the Niño 3.4 region from 1871 to 2008	20
13.	Annual and 10-yma values of November values of HadSST in the Niño 3.4 region from 1871 to 2008	21

LIST OF FIGURES (Continued)

14.	Annual and 10-yma values of December values of HadSST in the Niño 3.4 region from 1871 to 2008	22
15.	Monthly and 12-mma values of nonseasonally adjusted HadSST values from January 1871 to January 2010	27
16.	Monthly and 2-mma values of the seasonally adjusted values of HadSST anomaly (D(m2)) from February 1871 to January 2010, where shaded portions reflect occurrences of warm EN events (positive anomalies) and cold LN events (negative anomalies), respectively	27
17.	Presentation of 2-mma values of SOI (SOI(2)) anomaly from January 1871 to January 2010	30
18.	Results of epoch analysis for EN events, (a) D(m2) and (b) SOI(2)	31
19.	Results of epoch analysis for LN events, (a) D(m2) and (b) SOI(2)	32
20.	The ONI anomalies from January 1950 to January 2010, where shaded portions reflect occurrences of warm EN events (positive anomalies) and cold LN events (negative anomalies), respectively	33
21.	Duration against (a) max ONI for LN and EN events (1950 – 2008) and (b) max D(m2) for LN and EN events (1871 – 2008)	36
22.	RP-duration distributions for (a) EN events (1950–2008) based on D(m2), (b) LN events (1950–2008) based on D(m2), (c) EN events (2000–2009) based on ONI, and (d) LN events (2000–2009) based on ONI	37
23.	RP-duration distribution for (a) EN events (1871–2008) based on D(m2) and (b) LN events (1871–2008) based on D(m2)	37
24.	Decadal variation of (a) NENO, (b) NENM, (c) NLNO, and (d) NLNM based on D(m2). The 2009 EN event observed in ONI has been included with the 2000–2009 decade, even though HadSST values have not yet been published	39

LIST OF TABLES

1.	Annual and 10-yma values of SST in the Niño 3.4 region based on HadSST monthly time series from 1871 to 2008	7
2.	Frequency of occurrence of monthly high and low values of SST in the Niño 3.4 region based on HadSST values from 1871 to 2008	10
3.	HadSST monthly and 10-yma values for the Niño 3.4 region from 1871 to April 2009	23
4.	Listing of EN and LN events based on the HadSST dataset from 1871 to 2008	28
5.	Frequency of occurrence of start, peak, and end times for HadSST-determined EN and LN events	30
6.	Listing of EN and LN events based on ONI (ERSST.v3b)	34
7.	SST monthly values of the Niño 3.4 region in degrees Celsius based on HadSST time series, ONI and SOI values, and the occurrences of EN (warm) and LN (cold) events from 1871 to the present	44

LIST OF ACRONYMS AND ABBREVIATIONS

2-mma	2-month moving average
12-mma	12-month moving average
10-yma	10-year moving average
D(m)	difference between Hadley sea-surface temperature and the monthly-adjusted average (1871–2008)
D(m2)	2-mma of D(m)
DP	double peak
e	event end, based on Oceanic Niño Index
EN	El Niño
ENSO	El Niño Southern Oscillation
ERSST.v3b	Extended Reconstructed Sea-Surface Temperature, version 3b
HadSST	Hadley sea-surface temperature
H(M)	high (month)
L(M)	low (month)
LN	La Niña
M	moderate
MP	multiple peaks
NENM	number of EN months
NENO	number of EN onsets
NLNM	number of La Niña months
NLNO	number of La Niña onsets

LIST OF ACRONYMS AND ABBREVIATIONS (Continued)

ONI	Oceanic Niño Index
p	peak
RP	recurrence period
S	strong
s	event start, based on the Oceanic Niño Index
SOI	Southern Oscillation Index
SOI(2)	2-mma of Southern Oscillation Index
SP	single peak
SST	sea-surface temperature
VS	very strong
W	weak

NOMENCLATURE

cl	confidence level
CV	coefficient of variation
na	number above median
nb	number below median
nra	number of runs above median
PCS	Pearson Coefficient of Skewness
PI	prediction interval
r	coefficient of correlation
r^2	coefficient of determination
sd	standard deviation
se	standard error of estimate
x	independent variable in regression equation
y	dependent variable in regression equation
z	normal deviate for the sample

TECHNICAL PUBLICATION

AN EXAMINATION OF THE HADLEY SEA-SURFACE TEMPERATURE TIME SERIES FOR THE NIÑO 3.4 REGION

1. INTRODUCTION

The El Niño (EN) southern oscillation (ENSO) phenomenon has been described as the strongest oceanic-atmospheric tropical signal measured on interannual timescales.^{1–3} Although primarily perceived as a tropical Pacific event, as evinced by its strongly coupled sea-surface temperature (SST) and atmospheric pressure variations, the effects of ENSO impact Earth on a global scale.^{1,2,4–10}

El Niño and La Niña (LN), respectively, refer to the anomalous episodic warm and cold water phases of the ENSO variation, when based upon SST, and to the anomalous negative and positive atmospheric pressure phases, respectively, when based on the Southern Oscillation Index (SOI).^{11,12} During an EN event, the westerly trade winds along the Earth's equator weaken as atmospheric pressure rises in the western Pacific (Darwin, Australia) and falls in the eastern Pacific (Tahiti, French Polynesia). As a consequence of this action (called the Bjerknes feedback mechanism¹³), anomalous warming in the central and eastern Pacific occurs due to eastward migrating warm water from the western Pacific, which diminishes the strong cold-water upwelling off the South American coast.^{14,15} The reverse happens during an LN event (i.e., enhanced upwelling, positive SOI, and anomalous cooling in the eastern Pacific). When neither an EN nor a LN event is said to be occurring, conditions are more generally described as being ENSO neutral.

While the occurrences of EN events have been traced back hundreds of years, as gleaned from reports of anomalous rainfalls and storm events on coastal Peru, ship records, etc.,^{16–18} more recently, the use of SST, in particular those SST readings from the Niño 3.4 region (5° N.– 5° S., 120 – 170° W.) have provided the most reliable means for documenting the onsets, strengths, and durations of both EN and LN events. In fact, now, published monthly is the Oceanic Niño Index (ONI), a 2-month moving average (2-mma; also called the 3-month running mean) of the Extended Reconstructed SST, version 3b (ERSST.v3b) anomalies of the Niño 3.4 region, which provides an easily accessible means for monitoring the onsets, strengths, and durations of both EN and LN events, particular, from 1950 onwards.^{19,20}

On the basis of the ONI, an EN event is said to be occurring when the index value measures 0.5°C or warmer for at least 5 continuous months. An EN event is termed “weak (W)” when the peak positive warm anomaly measures 0.5 – 0.9°C , “moderate (M)” when the peak positive warm anomaly measures 1.0 – 1.4°C , and “strong (S)” when the peak positive warm anomaly measures 1.5°C or warmer. Similarly, an LN event is said to be occurring when the ONI measures -0.5°C or cooler for at least 5 continuous months. A LN event is termed W when the peak negative cool

anomaly measures -0.5 to -0.9 $^{\circ}\text{C}$, M when the peak negative cool anomaly measures -1.0 to -1.4 $^{\circ}\text{C}$, and S when the peak negative cool anomaly measures -1.5 $^{\circ}\text{C}$ or cooler.

Previously, the decadal variation of EN events was examined using the ONI-determined listing of EN events (1950–2008) to investigate whether it could possibly be related to global warming or more simply be a manifestation of natural variation.^{21,22} From that study, it was found that the decadal variation of the number of EN onsets was better explained as one expressing normal fluctuation rather than one related to global warming. Surprisingly, it was also inferred that, for M and S events, a statistically significant linear relationship (at the 2% level of statistical significance) was found to exist between the onset of the next EN event (the recurrence period (RP)) and the last known duration of an EN event, strongly suggesting that another EN event likely would have its onset in 2009, which turned out to be true. Because EN, indeed, recurred during 2009, a sharp reduction in the frequency of North Atlantic basin tropical cyclones during the 2009 hurricane season should have been expected and, indeed, was seen, with respect to earlier forecasts for the North Atlantic basin hurricane season.^{23–25}

In this study, the HadSST dataset for the Niño 3.4 region is examined to determine the onsets, strengths, and durations of EN and LN events during the interval 1871–2008.^{26,27} Also, comparison is made against both SOI values for the same time interval and the ONI-determined listing of ENSO extremes since 1950 to see what differences might possibly exist,²⁸ if any, especially with regard to the identification of the occurrence, strength, and duration of ENSO extremes. Additionally, the duration-maximum anomaly association for ENSO extremes and the RP-duration association, previously found for EN events using ONI, are investigated to determine if they also might exist using the HadSST dataset. Finally, decadal aspects of the ENSO extremes are examined, anticipating what possibly might lie ahead for the current decade (2010–2019).

2. RESULTS AND DISCUSSION

2.1 Annual Averages of HadSST in the Niño 3.4 Region (1871–2008)

Figure 1 displays (a) the annual mean and (b) annual high HadSST values in degrees Celsius for the interval 1871–2008 (shown as the thin jagged lines) and their 10-yr moving average (10-yma) values (shown as the thick smoothed lines). Figure 2 similarly shows (a) the annual low and (b) the annual difference (high minus low HadSST values) in degrees Celsius for the same time interval. For each temperature, the mean for the entire interval is plotted as the horizontal line: 26.95 °C for the annual means, 27.87 °C for the annual highs, 25.92 °C for the annual lows, and 1.97 °C for the annual differences. Also, for each panel, given are the standard deviation (sd), the coefficient of variation ($CV = sd/\text{mean}$), the median, the Pearson coefficient of skewness ($PCS = 3(\text{mean} - \text{median})/sd$), the number of annual values above the median (na), the number of annual values below the median (nb), the number of runs above the median (nra), the normal deviate for the sample results to determine whether the distributions are randomly distributed ($z = (nra - na(nb + 1))/(na(nb + 1)(na - 1)/(na + nb)^2(nb(na + nb - 1)))^{1/2}$), the highest and lowest annual value and their occurrence years, the 50% prediction interval (50% PI), the inferred regression equation based on linear regression analysis against time (y), the coefficient of correlation (r), the coefficient of determination (r^2 , a measure of the amount of variance explained by the inferred regression), the standard error of estimate (se), and the confidence level (cl) of the inferred regression, except for the annual lows since the inferred regression and the mean were essentially the same.

For the annual means (fig. 1a), one finds its highest value to have occurred in 1877, measuring 28.30 °C, and its lowest value to have occurred in 1890, measuring 25.78 °C. Runs testing indicates that the distribution of yearly means is nonrandomly distributed ($z = -2.38$). The inferred regression suggests a slight warming with time (about 0.00154 °C per yr), although the inferred regression is only of marginal statistical significance ($cl > 90\%$), suggesting that the inferred regression probably can be disregarded. In fact, the inferred long-term warming disappears if one neglects the earliest portion of the data (i.e., that part prior to about 1895). The nonrandom nature of the distribution of annual means may simply be a reflection of its decadal variation (represented by the thick smoothed line). The decadal variation is strikingly upward from about 1950 to 1995, increasing from 26.68 °C in 1951 to 27.28 °C in 1994, with large peaks in 1962 and 1982, a large dip in 1971, and a shallow dip in 1985. Since 1994, the trend in decadal values has been downward, falling below the long-term mean in 2003. About 25% of the time, the annual mean is found to exceed 27.34 °C, and about 25% of the time it falls below 26.56 °C.

For both the annual high (fig. 1b) and low values (fig. 2a), one finds similar episodic behavior (i.e., based on the 10-yma values) akin to that of the annual means, although the behavior demonstrated by the lows seems strikingly more pronounced. While the annual highs appear to be randomly distributed, the lows, in contrast, appear to be nonrandomly distributed (like the annual means). Neither the annual highs nor lows have statistically significant inferred upward linear regressions against time. For the highs, the highest high occurred in 1878, measuring 29.19 °C, and the lowest

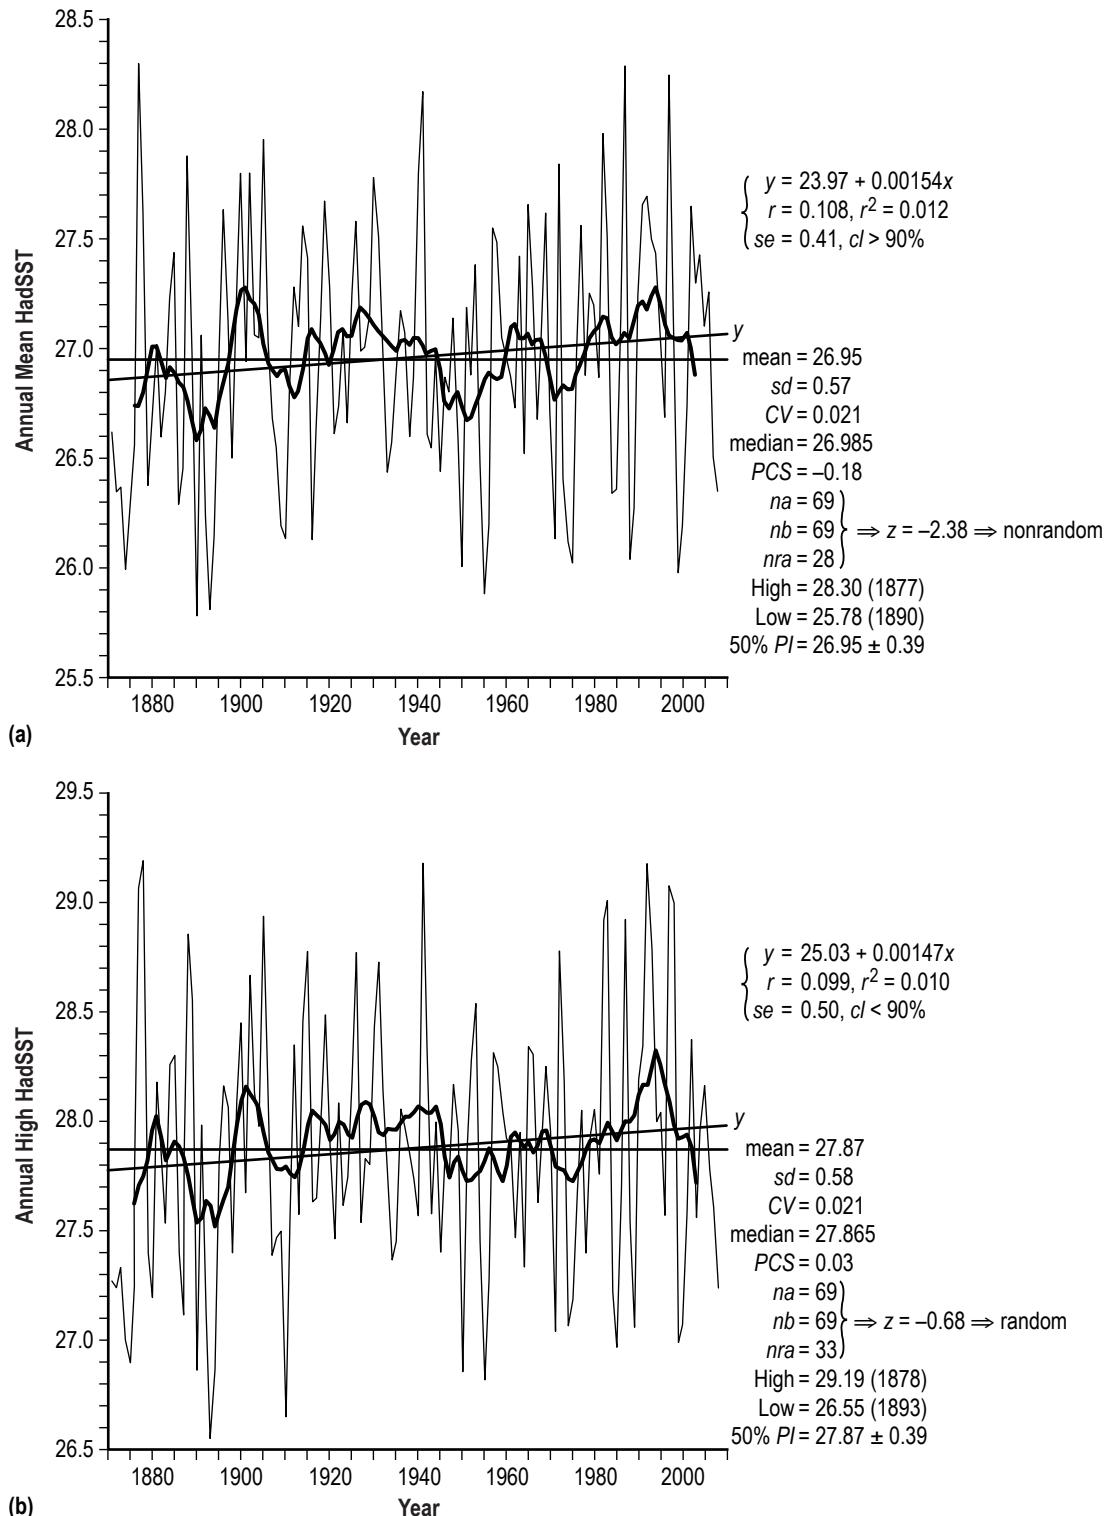

Figure 1. Annual and 10-yma values of (a) mean and (b) high values of HadSST in the Niño 3.4 region from 1871 to 2008.

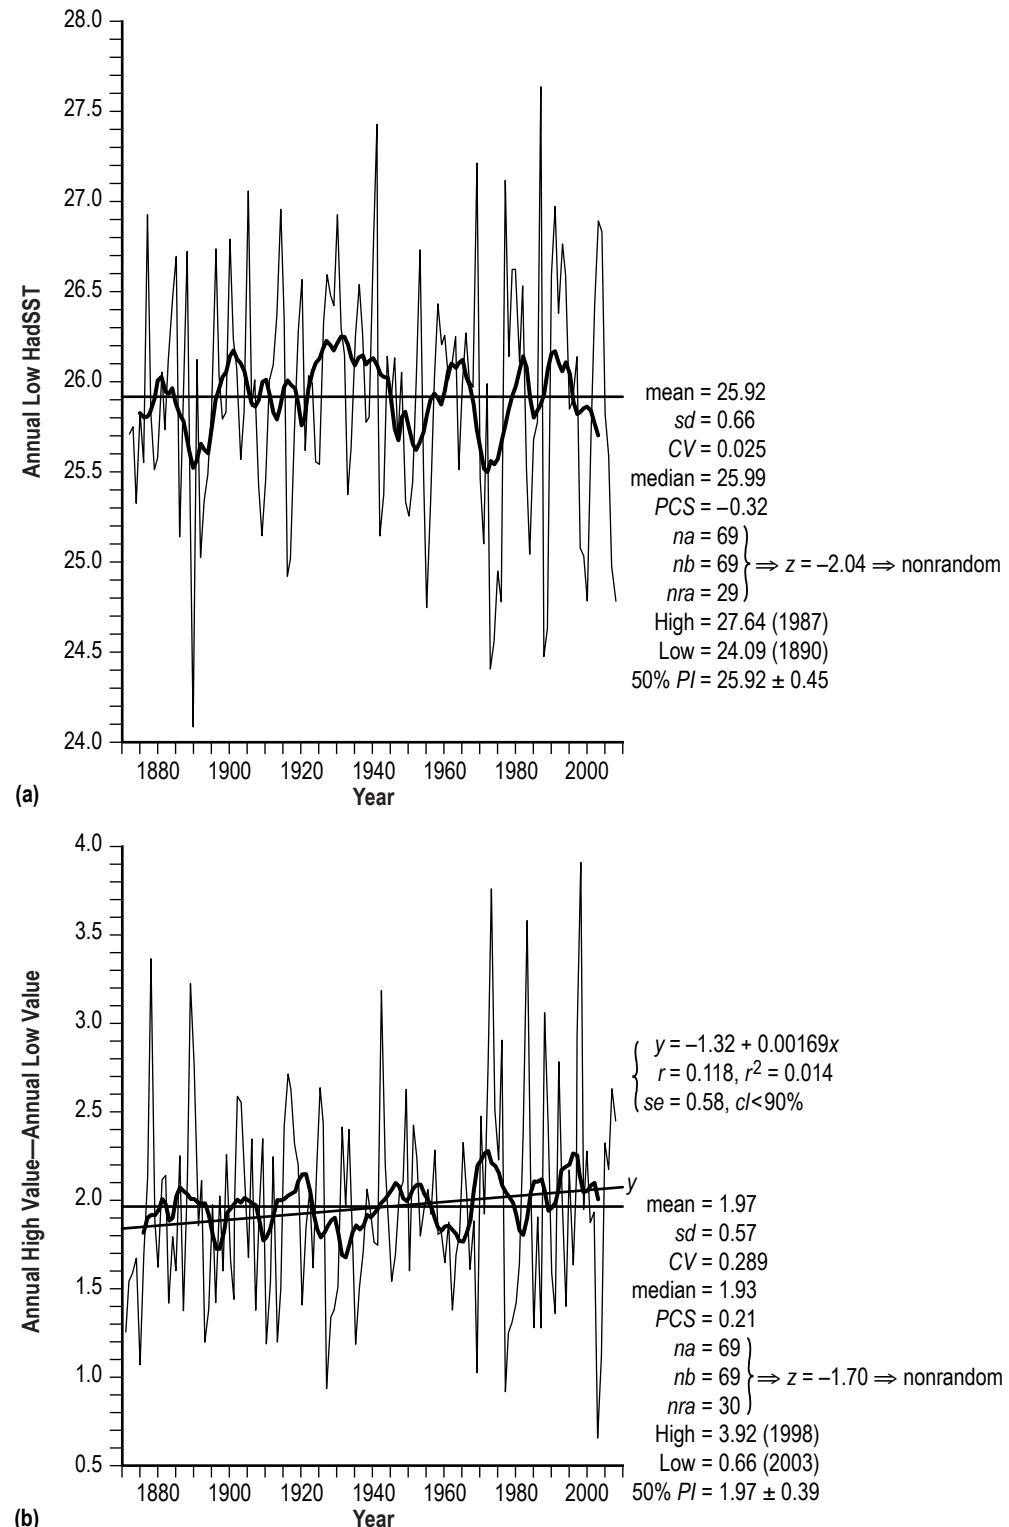

Figure 2. Annual and 10-yma values of (a) low values and (b) differences (high minus low) of HadSST in the Niño 3.4 region from 1871 to 2008.

high occurred in 1893, measuring 26.55 °C. For the lows, the highest low occurred in 1987, measuring 27.64 °C, and the lowest low occurred in 1890, measuring 24.09 °C. The 10-yma values for both the annual highs and lows have recently fallen to values below their respective long-term means.

Figure 2b plots the annual difference between the high minus low values. The annual differences appear to be nonrandomly distributed, with the highest difference occurring in 1998, measuring 3.92 °C, and the lowest difference occurring in 2003, measuring 0.66 °C. The inferred regression is not statistically important. The 10-yma values of the differences currently remain above its long-term mean, although they appear to be decreasing with time and may soon fall below its long-term mean.

For convenience, table 1 is included, which provides a listing of the annual means, highs, lows, and differences, as well as their 10-yma values and statistical aspects for each year and each grouping of SST values. Additionally, the listing identifies the month within each year when the extremes (lows and highs) occurred. Table 2 gives the frequency distribution of the monthly occurrences of the extremes. One finds that more than 80% of the time, the highest yearly value occurs in the months of April, May, and June, while, more than 80% of the time, the lowest yearly value occurs in the months of November, December, and January. Obviously, a strong seasonal effect exists within the HadSST data that must be removed if one seeks to correctly describe the occurrences, strengths, and durations of EN and LN events (i.e., any anomalies that might be embedded in the time series).

Figures 3–14 display individually the monthly values, January thru December, for the 138-yr history of HadSST measurements (1871–2008). The plots are constructed similar to figures 1 and 2, giving each year's monthly value as the thin jagged line and the 10-yma as the thick smoothed line, with the statistics identified for each month given to the right. Five months display nonrandom variations, including January, March, April, June, and July, with the remainder displaying random variations. Table 3 summarizes the mean and 10-yma values for each month, as well as giving various statistics for each month.

2.2 Monthly and 12-mma Values of HadSST in the Niño 3.4 Region (1871–2008)

Figure 15 displays the nonseasonally adjusted monthly means of HadSST for 1871–2008.²⁷ The thin jagged line is the monthly mean and the thick smoothed line is the 12-mma value. The horizontal line is the mean for the entire interval (1871–2008). Clearly, the variation of the 12-mma values of HadSST is episodic, displaying values both lower and higher than the long-term mean. Cooler 12-mma values of HadSST suggest the occurrences of LN-like conditions, while warmer 12-mma values of HadSST suggest the occurrences of EN-like conditions. Since about mid 2007, the 12-mma values of HadSST have been cooler than the long-term mean, reflecting LN-like conditions, although the current trend has been upward towards warmer values (since December 2007). EN-like conditions seemed certain to prevail in the latter half of 2009 (HadSST monthly values have been published only thru April 2009, meaning that 12-mma values of HadSST can only be computed up thru October 2008). In fact, based on ONI, EN-like conditions, indeed, first appeared in June 2009 and have continued through the end of the year, indicating the occurrence of an EN event, one that had been predicted in the earlier study.²¹ (ONI = 1.8 °C in December 2009, a value indicative of an S EN event.)

Table 1. Annual and 10-yma values of SST in the Niño 3.4 region based on HadSST monthly time series from 1871 to 2008.

Year	Mean SST	10-yma	sd	L(M)	10-yma	H(M)	10-yma	H(M)–L(M)	10-yma	Median	CV	PCS
1871	26.61	–	0.41	26.01(12)	–	27.27(04)	–	1.26	–	26.525	0.015	0.62

na	69			69		69		69				
nb	69			69		69		69				
nra	28			29		33		30				
z	-2.38			-2.04		-0.68		-1.70				
random?	no			no		yes		yes				
±50% PI	0.39			0.45		0.39		0.39				
CV	0.021			0.025		0.021		0.289				
PCS	-0.18			-0.32		0.03		0.21				

Notes: Mean SST = monthly mean sea surface temperature in the year, based on the Hadley dataset and measured in degrees Celsius.

sd = standard deviation.

L(M) = lowest monthly value in the year and the month it occurs.

H(M) = highest monthly value in the year and the month it occurs.

H–L = range.

na = number of yearly values above the median.

nb = number of yearly values below the median.

nra = number of runs above the median value.

z = normal deviate calculated from nra, na and nb; when z <-1.96 or >1.96, hypothesis testing suggests that the distribution is nonrandom.

PI = prediction interval.

CV = coefficient of variation, equal to sd/Mean SST.

PCS = Pearson coefficient of skewness, equal to 3(Mean SST – Median)/sd.

* = also following month.

& = also seen in November 1893.

M refers to local maximum values within a string of yearly values.

m refers to local minimum values within a string of yearly values.

Table 2. Frequency of occurrence of monthly high and low values of SST in the Niño 3.4 region based on HadSST values from 1871 to 2008.

Month	Monthly High Value Occurrence		Monthly Low Value Occurrence	
	f	Percent	f	Percent
01	7	0.051	58	0.420
02	1	0.007	7	0.051
03	2	0.014	0	0.000

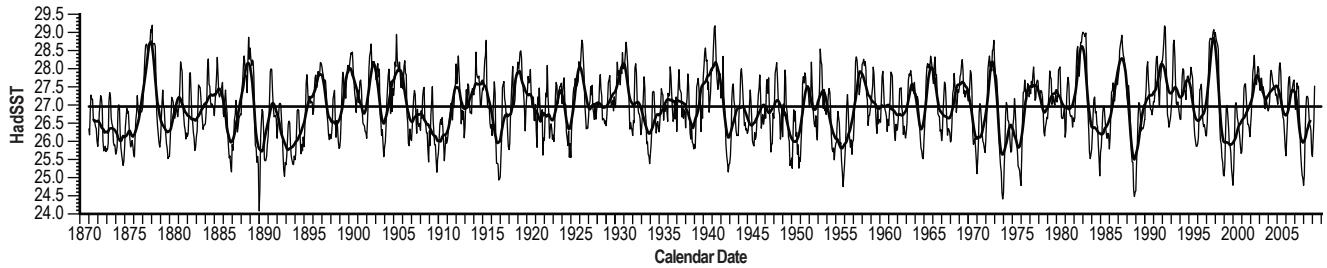

Figure 15. Monthly and 12-mma values of nonseasonally adjusted HadSST values from January 1871 to January 2010.

2.3 2-mma Values of Seasonally Adjusted Monthly Means of HadSST (D(m2)) and SOI (SOI(2)) in the Niño 3.4 Region (1871–2008)

Figure 16 depicts the 2-mma values of the seasonally adjusted monthly means of HadSST (D(m2)), where the shaded portions represent anomalous ENSO extreme events. The seasonally adjusted values were determined by subtracting the long-term monthly averages from the observed HadSST monthly values, then performing a 2-mma of the differences, with determination of anomalous HadSST ENSO extremes (based on D(m2) values) following that used in the determination of ONI anomalous ENSO extreme events (see section 1).

From figure 16, some 33 EN and 27 LN events are identified. For convenience, the listing of EN and LN events is given in table 4, identifying the start, peak, and end dates (by year-month); the duration of each event (in months); the event type (EN or LN); the strength of each event, both in terms of class strength (i.e., W, M, and S) and peak anomalous temperature in degrees Celsius; and comments, where SP means single peak, DP means double peak, and MP means multiple peaks (three or more).

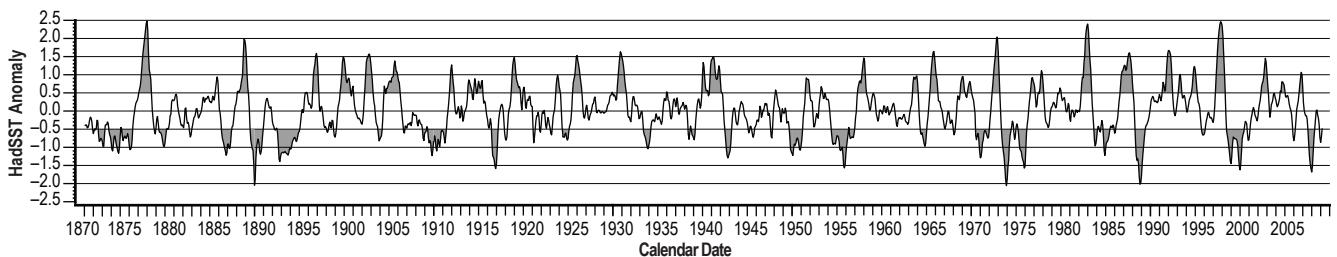

Figure 16. Monthly and 2-mma values of the seasonally adjusted values of HadSST anomaly (D(m2)) from February 1871 to January 2010, where shaded portions reflect occurrences of warm EN events (positive anomalies) and cold LN events (negative anomalies), respectively.

Table 4. Listing of EN and LN events based on the HadSST dataset from 1871 to 2008.

Notes * VS = very strong events are those where the anomaly exceeds the ± 2 degree threshold.

SP = single peak.

DP = double peak.

MP = multiple peaks (three or more).

Of the 33 EN events, 9 are considered W, 11 are M, and 13 are S or very strong (VS) in strength. The greatest positive anomalies (EN events classified as VS) occurred in January 1877 (+2.48 °C), November/December 1972 (+2.03 °C), January 1983 (+2.40 °C), and November 1997 (+2.46 °C). The longest duration EN event was 19 months in length, occurring between October 1904 and April 1906. The average duration (± 1 *sd*) of EN events is 10.3 ± 4.2 months. Twenty-one of 33 EN events were single peaked, 12 were double peaked, and none had 3 or more peaks.

Of the 27 LN events, 9 are considered W, 10 are M, and 8 are S or VS. The greatest negative anomalies (LNs classified as VS) occurred in January 1890 (-2.04 °C), December 1973 (-2.05 °C), and November 1988 (-2.01 °C). The longest duration LN event was 31 months in length, occurring between June 1954 and December 1956. The average duration of LN events is 13.3 ± 7.2 months. Fifteen of 27 LN events were single peaked, 6 were double peaked, and 6 had multiple peaks.

Table 5 shows the frequency of occurrence of EN and LN event starts, peaks, and ends for selected monthly intervals. Hence, half (30 of 60 events) of all EN and LN events have onset during the interval July to October, nearly all peak (52 of 60 events) during the interval November to February, and slightly more than half (36 of 60 events) end during the interval of March to June.

Table 5. Frequency of occurrence of start, peak, and end times for HadSST-determined EN and LN events.

Monthly Interval	EN(33)			LN(27)		
	Start	Peak	End	Start	Peak	End
November–February	8	26	9	2	26	9
March–June	9	3	18	11	1	18
July–October	16	4	6	14	0	0

Figure 17 displays the 2-mma values of the SOI (SOI(2)) for the interval 1871–present. Recall that extended intervals of positive SOI reflect LN-like conditions while extended intervals of negative SOI reflect EN-like conditions. Comparison of the 2-mma of SOI(2) (fig. 17) against D(m2) (fig. 16) reveals a strong negative correlation between the two parameters, having $r = -0.84$, based on the interval 1971–2000 (the base period used in determination of the ONI), although, plainly, SOI(2) sometimes leads and sometimes lags D(m2). The overall negative correlation weakens if one uses the entire interval 1871–2008, suggesting, perhaps, that the early occurring values, in particular, of D(m2) (and hence, HadSST) might not be as reliable as compared to later occurring values. The strongest negative anomalies (usually associated with EN events) occurred in August 1882 (-21.8), May/June 1896 (-31.0), April 1905 (-38.2), February 1983 (-31.3), May 1987 (-21.9), and March 1998 (-25.2). The strongest positive anomalies (usually associated with LN events) occurred in December 1872 (27.9), August 1879 (21.5), December 1889 (22.0), April 1904 (20.5), August 1917 (31.9), June 1950 (20.6), November 1973 (22.5), and August 1975 (21.3).

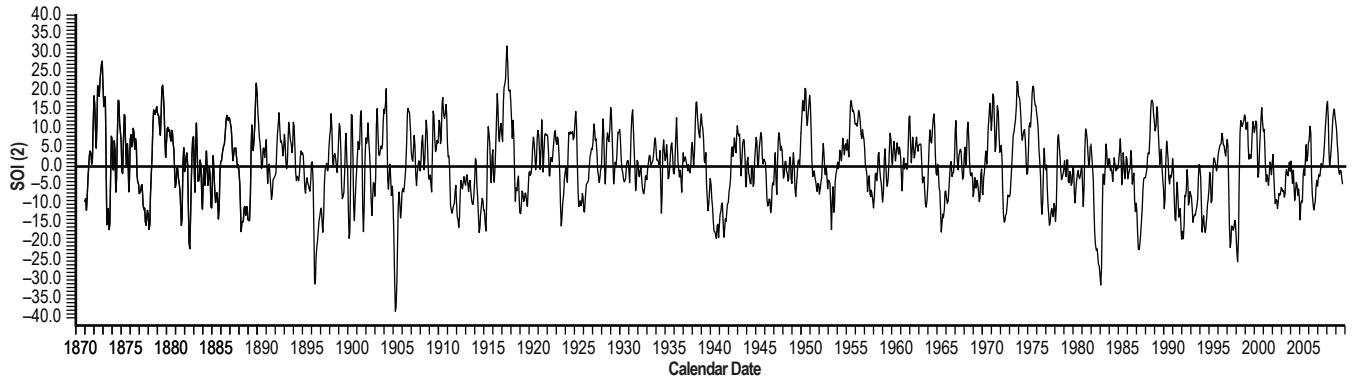

Figure 17. Presentation of 2-mma values of SOI (SOI(2)) anomaly from January 1871 to January 2010.

Figures 18 and 19, respectively, depict the results of epoch analyses for the 33 EN and 27 LN events catalogued in table 4 in terms of D(m2) (upper panels) and SOI(2) (lower panels) and strength, where 1 represents W events, 2 M events, and 3 S and VS events. As expected, S events are more likely to have a later-occurring peak and a longer duration than events of lesser strength (true using D(m2) or SOI(2)).

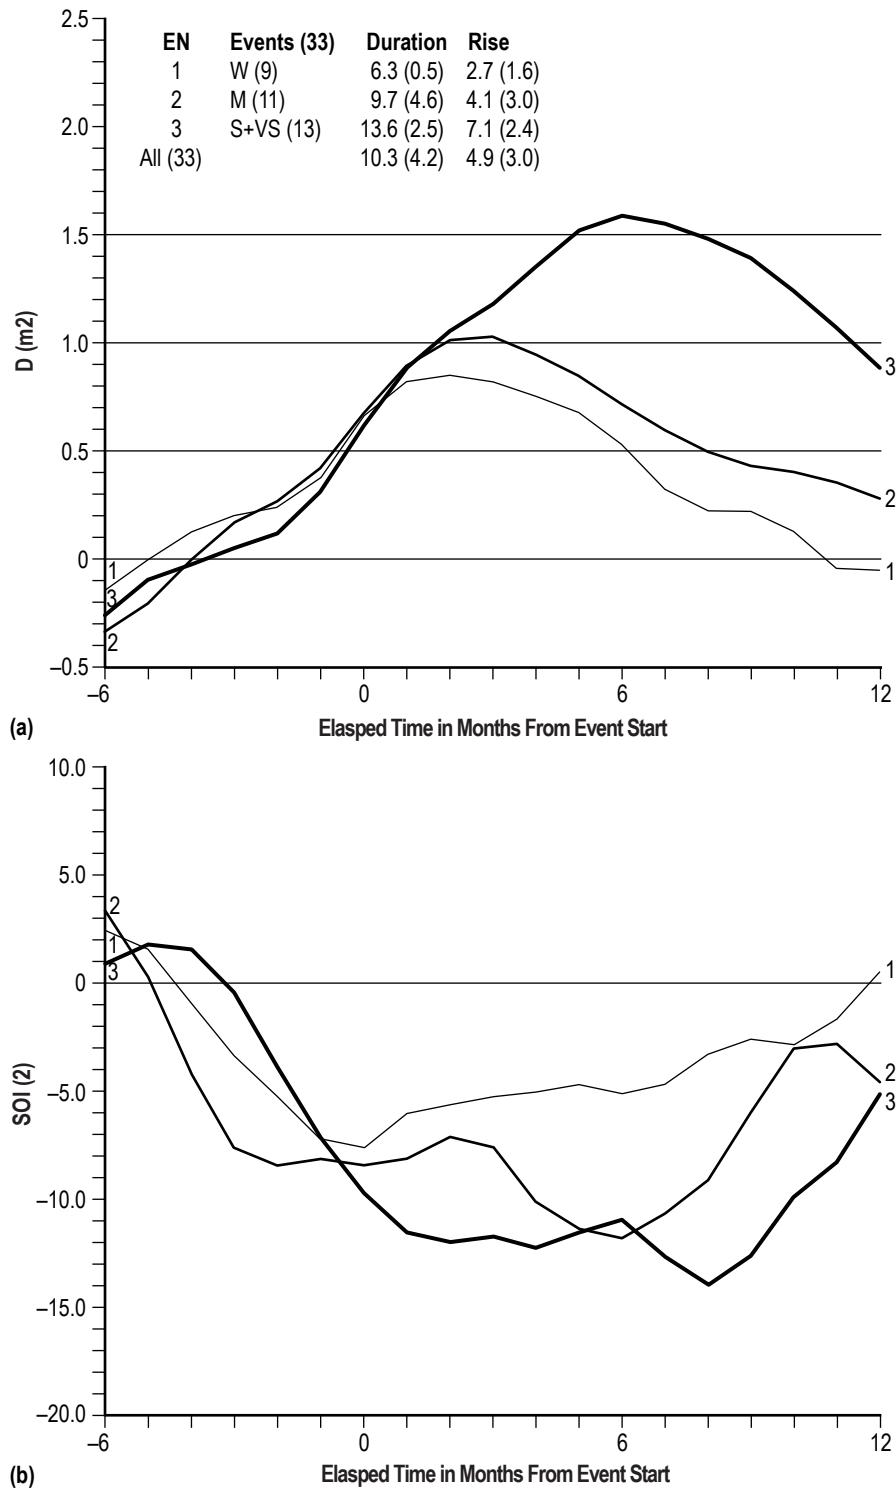

Figure 18. Results of epoch analysis for EN events, (a) $D(m^2)$ and (b) $SOI(2)$.

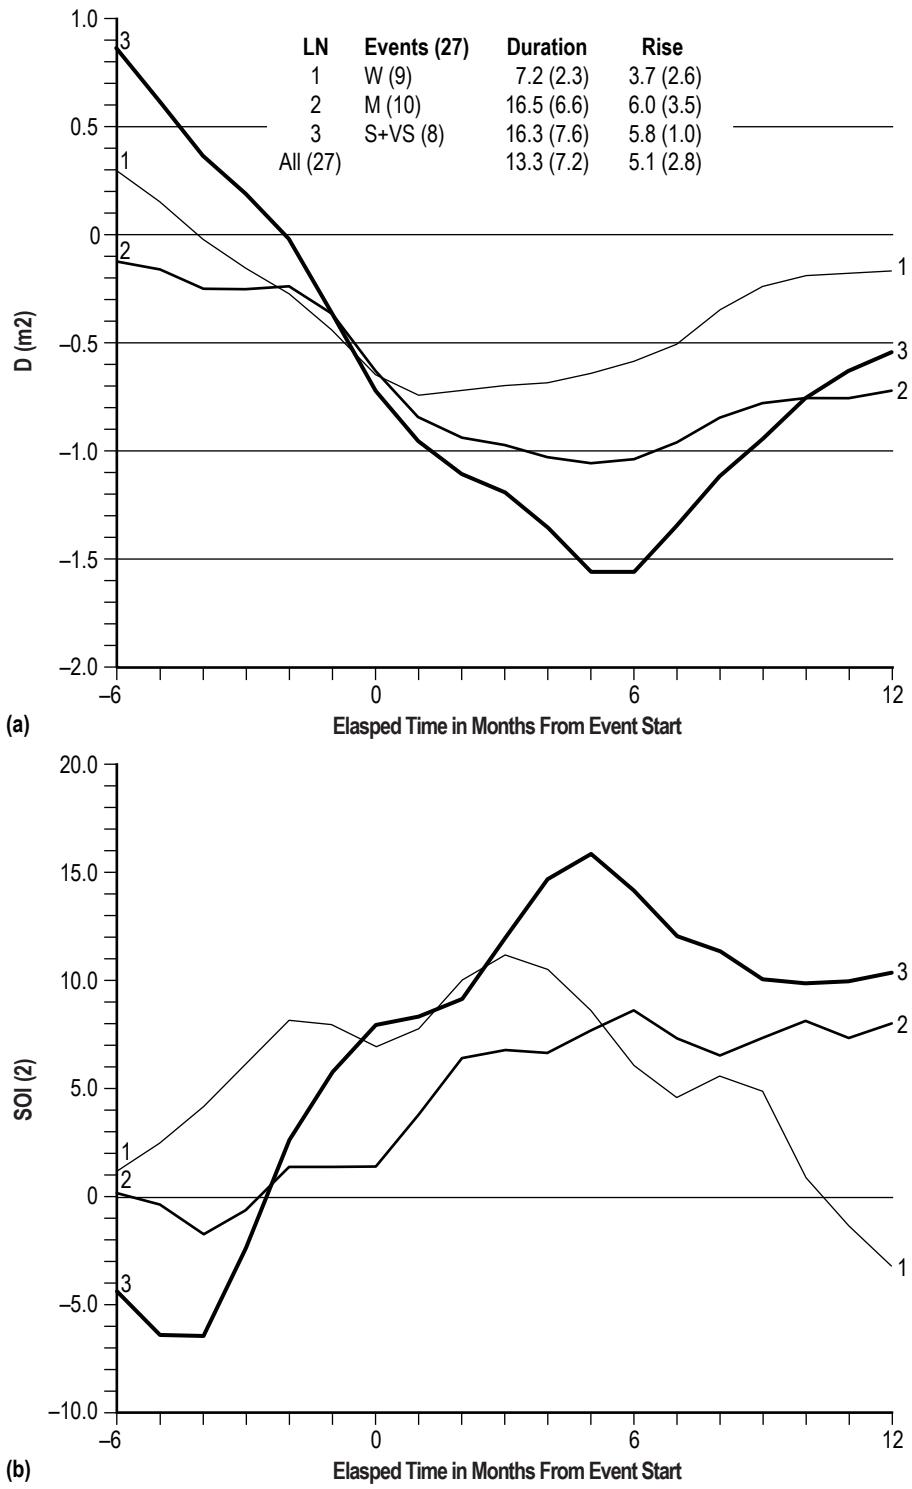

Figure 19. Results of epoch analysis for LN events, (a) $D(m^2)$ and (b) $SOI(2)$.

2.4 The ONI Values in the Niño 3.4 Region (1950–2008)

Figure 20 displays the ONI values for the interval 1950–present, plotted akin to that employed in figure 16 for D(m2). Again, the shaded portions of the figure denote the occurrences of the extremes of the ENSO cycle, where positive anomalies represent EN events and negative anomalies represent LN events. From figure 20, one can identify 31 extreme events, consisting of 18 EN and 13 LN events (since 1950). Recall from figure 16 that, for the same time interval (i.e., since January 1950), one can identify 30 extreme events using D(m2), as well, consisting of 18 EN events and 12 LN events, with the most recent 2009 EN event not included in figure 16. Hence, there appears generally good agreement in identifying the occurrences and strengths of the extremes using the two datasets. While true, some subtle differences are found. For example, in figure 16, the D(m2) LN event of 1973 began in June 1973 and ended in June 1974 with another separate LN event following in April 1975 that ended in March 1976. In figure 20, the ONI records the 1973 LN event as starting in May 1973 and being one long continuous event that ended in May 1976. Another difference is the inclusion of an LN event in 1983 in figure 16 but not included in figure 20, the inclusion of an EN event in 1993 in figure 16 but not included in figure 20, and the inclusion of a LN event in 2000 in figure 20 but not in figure 16. For the ONI-identified extremes, LN and EN events are found to average, respectively, about 15.0 and 10.1 months in duration, while for the same interval, the D(m2)-identified extremes of LN and EN events are found to average, respectively, about 13.7 and 9.2 months in duration. It appears then that extremes identified using the ONI values tend to be slightly longer in duration than when identified using D(m2). For convenience, table 6 is included, giving the event start, peak, and end times; duration; type; strength; and comments for the ONI-determined EN and LN events, constructed similar to that of table 4, which identified extremes using D(m2).

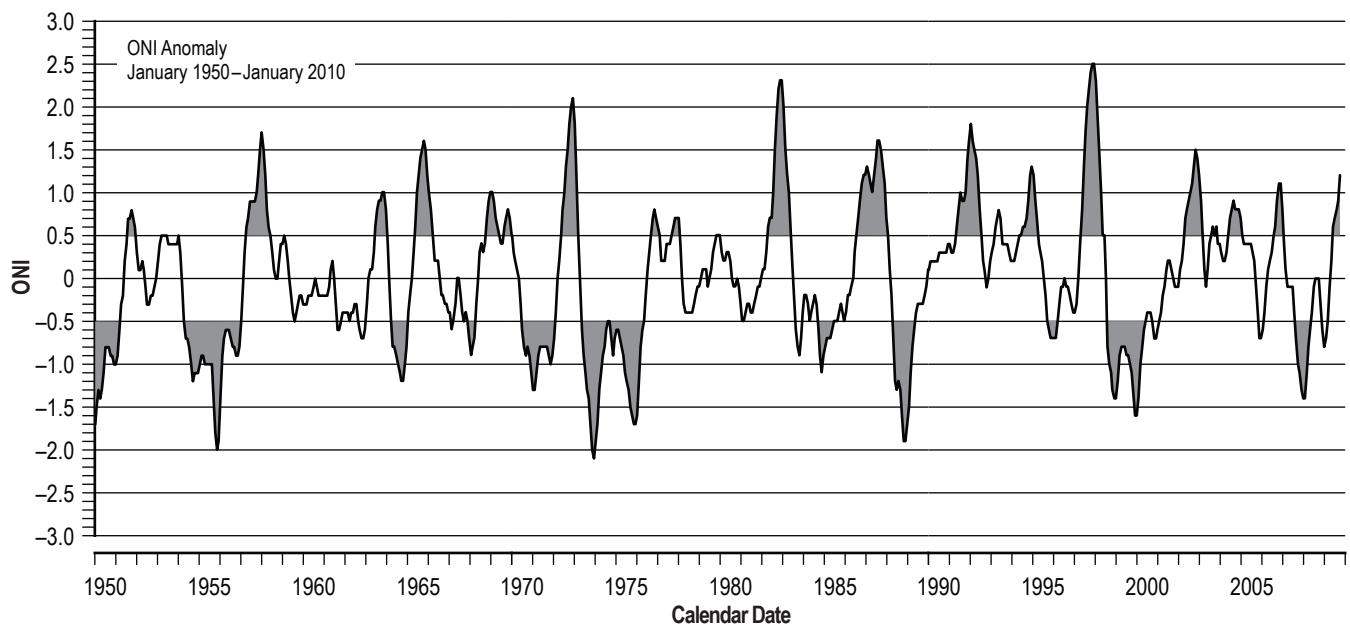

Figure 20. The ONI anomalies from January 1950 to January 2010, where shaded portions reflect occurrences of warm EN events (positive anomalies) and cold LN events (negative anomalies), respectively.

Table 6. Listing of EN and LN events based on ONI (ERSST.v3b).

Correlation analysis of ONI and D(m2) during the ONI base period of 1971–2000 shows that the two parameters are highly correlated, having $r = 0.99$. The inferred regression equation between ONI and D(m2) using ONI as the independent variable is $D(m2) = -0.047 + 0.991\text{ONI}$ ($se = 0.130 \text{ }^{\circ}\text{C}$) and the inferred regression equation between ONI and D(m2) using D(m2) as the independent variable is $\text{ONI} = 0.048 + 0.989D(m2)$ ($se = 0.130 \text{ }^{\circ}\text{C}$).

2.5. The Duration-Maximum Anomaly Association for ENSO Extreme Events

Figure 21 shows the scatter plots of (a) the duration of EN and LN events against their maximum anomalous excursion temperature using ONI (max ONI) for the interval 1950–2008 and (b) the duration of EN and LN events against their maximum anomalous excursion temperatures

using $D(m2)$ (max $D(m2)$) for the interval 1871–2008. In both panels, the larger filled circles represent two events, both having the same duration and maximum anomaly excursion temperature. In figure 21, one finds the association between the duration of an ENSO extreme event (i.e., EN and LN events) and the maximum anomalous excursion to be statistically important. Hence, knowing the maximum value of the anomaly, one can estimate the duration of the event (at least its minimum length). For example, an EN event having $\text{max ONI} \geq 1.3^\circ\text{C}$ has always had a duration ≥ 11 months; whereas, an EN event having $\text{max ONI} < 1.3^\circ\text{C}$ has always had a duration < 11 months. The 2009 EN event, having had a $\text{max ONI} = 1.8^\circ\text{C}$, therefore is not expected to end until May 2010 or later, based on the inferred preferential association. Based on $D(m2)$, an EN event having $\text{max } D(m2) \geq 1.45^\circ\text{C}$ has always had a duration ≥ 9 months; whereas, an EN event having $\text{max } D(m2) < 1.45^\circ\text{C}$ almost always has had duration < 9 months. For a LN event having max ONI ($\text{max } D(m2)$) equal to -1.25°C (-1.23°C) or cooler, one expects a duration of 13 months (11 months) or longer; whereas, for a LN event having max ONI ($\text{max } D(m2)$) equal to -1.2°C (-1.22°C) or warmer, one expects a duration of 12 months (10 months) or shorter.

It is apparent from figure 21 that LN events tend to be longer in duration than EN events, sometimes extending about 3 years in duration. El Niño events appear to have never extended longer than about a year-and-a-half in duration.

2.6. Recurrence Periods of the ENSO Extremes

Figure 22 depicts (a) RP against duration for the EN events (1950–2008) using $D(m2)$, (b) RP against duration for the LN events (1950–2008) using $D(m2)$, (c) RP against duration for the EN events (1950–2009) using ONI, and (d) RP against duration for the LN events (1950–2009) using ONI. For each panel, the thin vertical and horizontal lines represent the medians of the parameters, and the symbols refer to S or VS events (filled triangles), M events (filled squares), and W events (filled circles). Also, for each panel, the Fisher's exact test for 2×2 contingency tables is applied. Figure 21c shows that there is a statistically significant association between RP and the duration for EN events during the interval 1950–2009 when based on ONI, one having $P = 1.3\%$, meaning that the probability of obtaining the observed distribution, or one more suggestive of a departure from independence, is computed to be $P = 1.3\%$. Using $D(m2)$ (fig. 21a), however, one computes $P = 23.8\%$, inferring a statistically unimportant association. For LN events (figs. 21b and c), neither descriptor appears to be statistically important.

Figure 23 plots RP against duration for (a) EN and (b) LN events for the expanded interval 1871–2008 using $D(m2)$. For EN events, the distribution of RP against duration now has $P = 0.1\%$, inferring a highly statistically important association. Also, for EN events, linear regression analysis suggests that RP is highly statistically related to duration, having $r = 0.68$ ($se = 25.1$ months). Thus, as duration for an EN event increases, there is a strong tendency for the RP to increase such that those EN events having duration of 11 months or more usually have an $RP \geq 39$ months (true for 13 of 16 EN events), and those having durations 10 months or less usually have an $RP < 39$ months (true for 13 of 16 EN events). For LN events, $P = 50.0\%$, inferring that the distribution results from chance. (In figure 22a, the large filled triangle at duration equal to 13 months and RP equal to 60 months is really two EN events, one of S and one of M strength.)

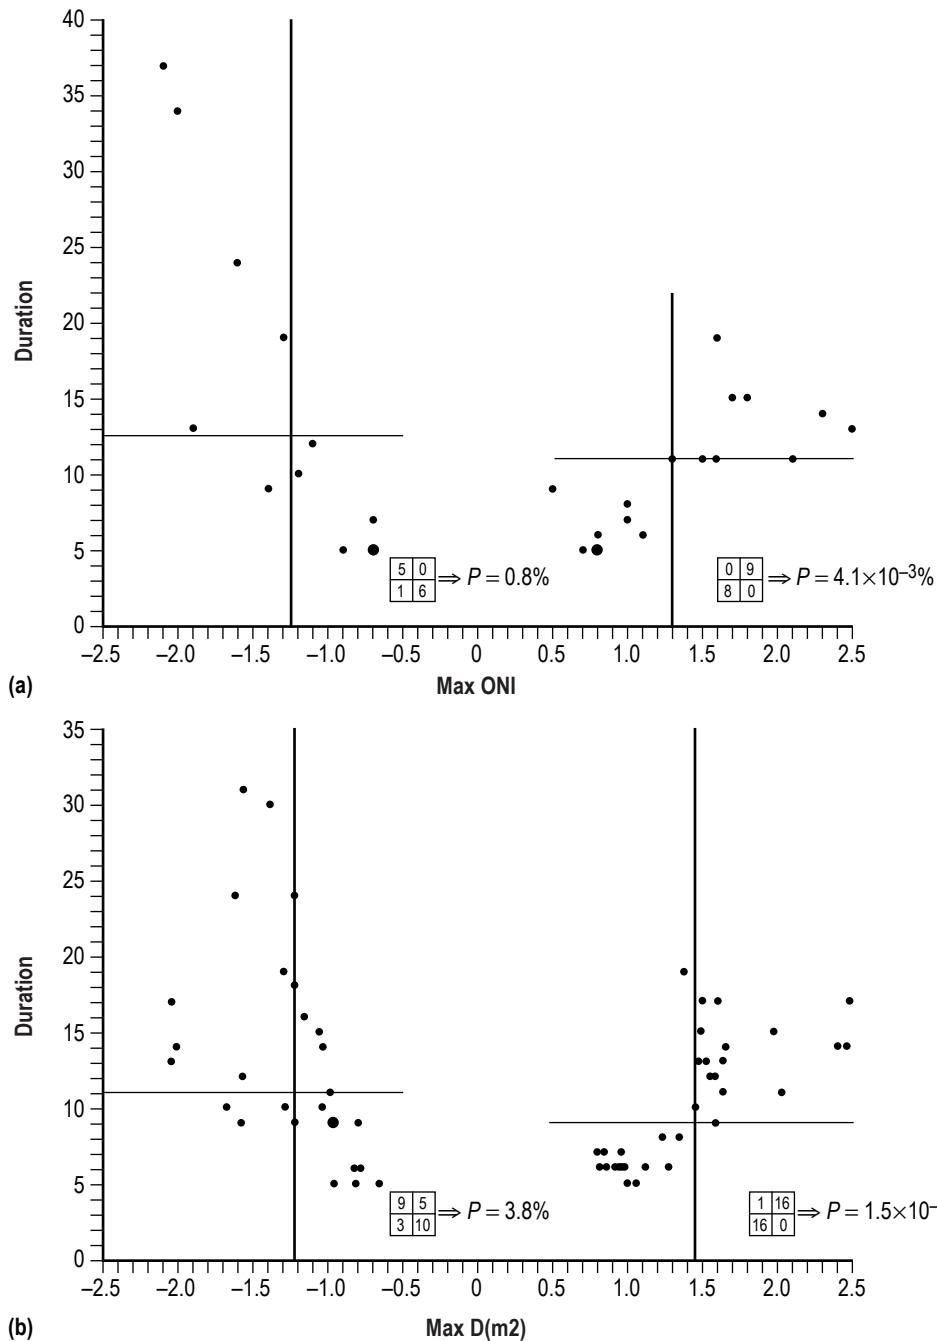

Figure 21. Duration against (a) max ONI for LN and EN events (1950 – 2008) and (b) max D(m2) for LN and EN events (1871 – 2008).

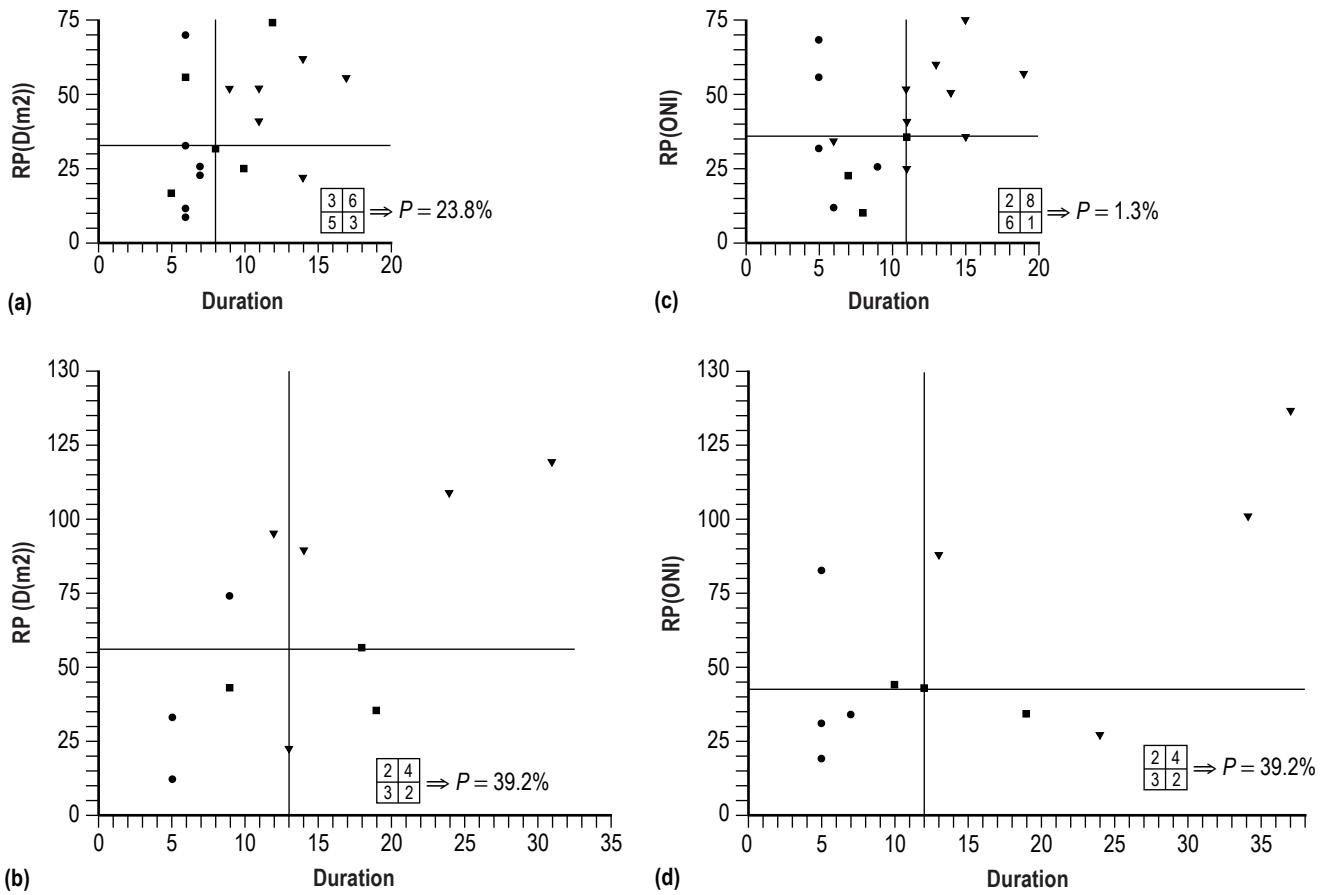

Figure 22. RP-duration distributions for (a) EN events (1950–2008) based on D(m2), (b) LN events (1950–2008) based on D(m2), (c) EN events (2000–2009) based on ONI, and (d) LN events (2000–2009) based on ONI.

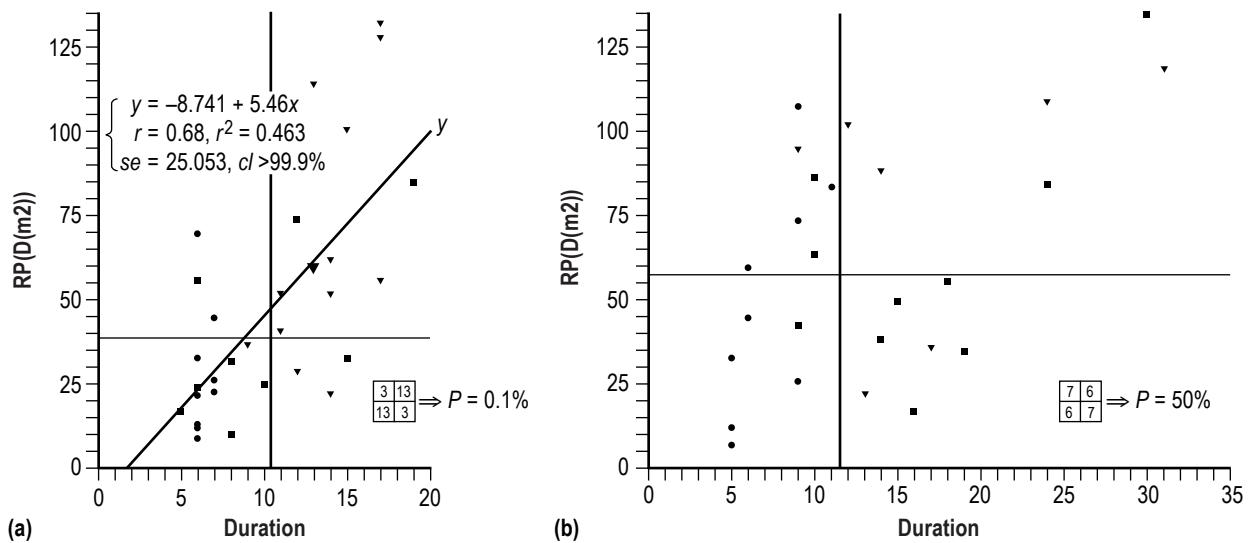

Figure 23. RP-duration distribution for (a) EN events (1871–2008) based on D(m2) and (b) LN events (1871–2008) based on D(m2).

2.7 Decadal Aspects of ENSO Extremes

Figure 24 displays (a) the number of EN onsets (NENO), (b) the number of EN months (NENM), (c) the number of LN onsets (NLNO), and (d) the number of LN months (NLNM) per decade (i.e., 1870–1879, 1880–1889, etc.) based on D(m2). For EN events, there has always been at least one EN onset occurring per decade, with two EN onsets per decade occurring about half of the time. The most number of EN onsets per decade has been four during the decades of 1900–1909, 1960–1969, 1990–1999, and 2000–2009. For LN events, there has always been at least one LN onset occurring per decade, which also is the most frequently observed rate, having occurred about half of the time. Decades of three or more LN onsets per decade include 1870–1879, 1900–1909, 1970–1979, and 1980–1989. During the last decade, only one LN event had an onset, the LN event of August 2007 (10-month duration).

For EN events, the NENM has been strikingly upwards since the decade of 1920–1929, as evinced by the inferred regression line. Presuming the validity of the inferred regression, extrapolation to the present decade (2010–2019), one projects NENM to be equal to about 37 ± 3 months (using the midpoint of the decade, 2014.5 in the regression), which suggests that one should expect about 3–4 EN onsets during the present decade. Based on the 2×2 contingency table, while there appears to be a loose association between NENM and decadal time, the probability of obtaining the observed distribution, or one more suggestive of independence, is $P = 14.3\%$, indicating that the overall behavior possibly could be due to chance. The two largest NENM (41 months) occurred during the decades of 1900–1909 and 1990–1999.

For LN events, a strikingly downward progression is inferred for NLNM between the decades of 1870–1879 and 1940–1949. Since the decade of 1940–1949, however, NLNM has shown no distinctive pattern, sometimes being above and sometimes being below the median (22.5 months). The highest NLNM values occurred in the decades of 1870–1879 (48 months), 1950–1959 (46 months), and 1970–1979 (44 months). For the past decade (2000–2009), there were only 10 LN months, as previously noted (the August 2007 LN event).

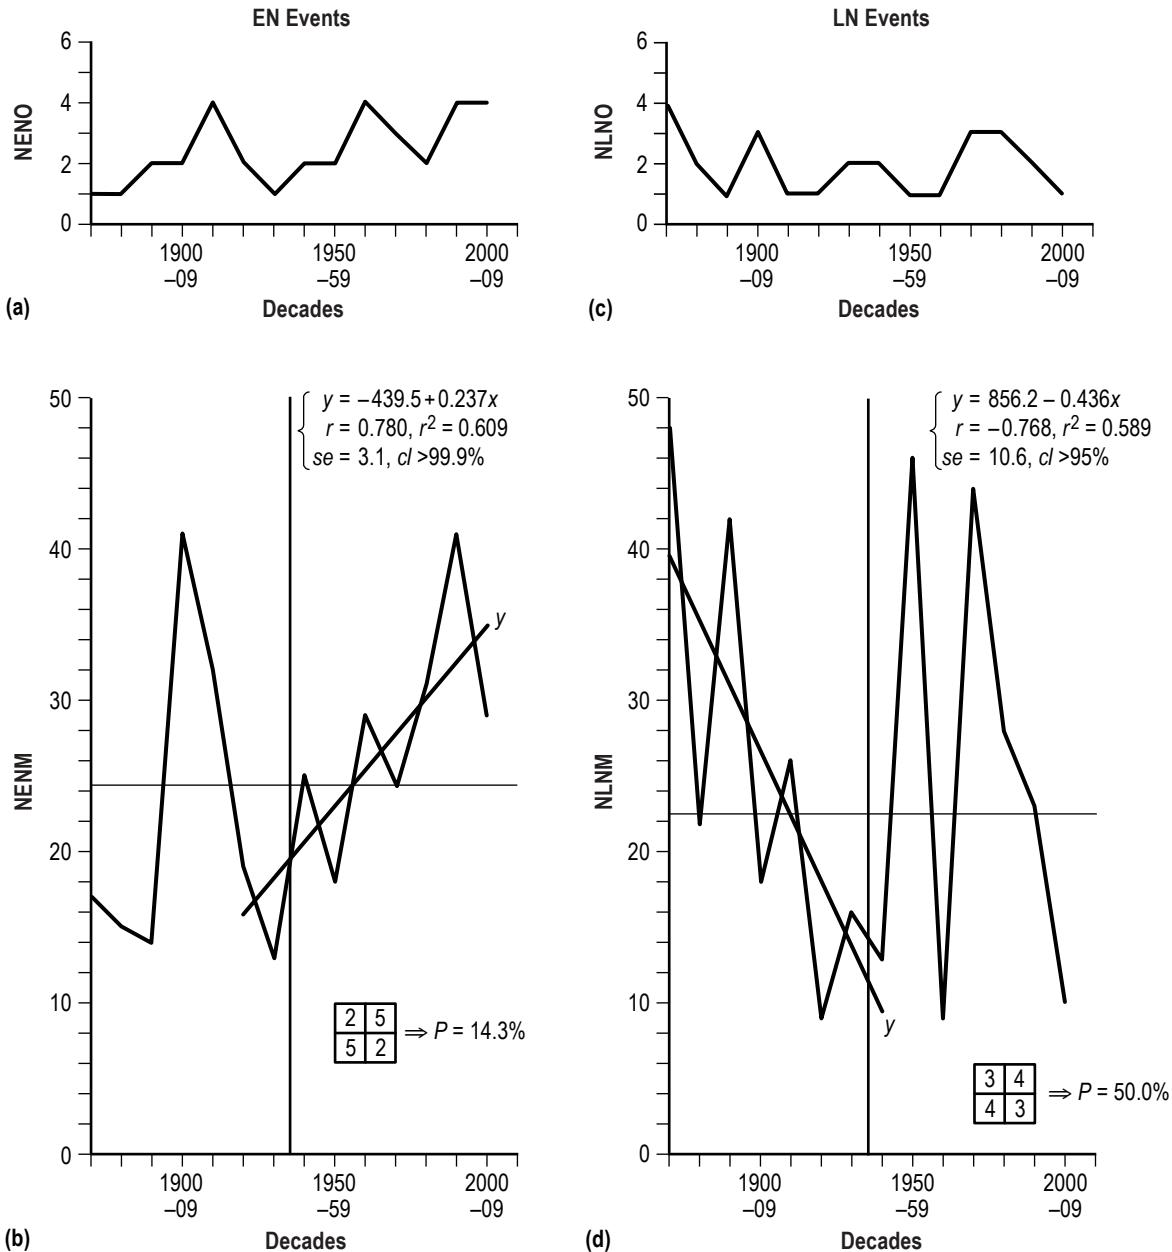

Figure 24. Decadal variation of (a) NENO, (b) NENM, (c) NLNO, and (d) NLNM based on D(m²). The 2009 EN event observed in ONI has been included with the 2000–2009 decade, even though HadSST values have not yet been published.

3. SUMMARY

This study has examined the HadSST dataset for the Niño 3.4 region for the interval 1871–present,^{26,27} investigating the onsets, strengths, and durations of EN and LN events. Also, comparison was made against both SOI values for the same time interval and the ONI-determined listing of ENSO extremes since 1950 to see what differences might possibly exist, if any, especially with regard to the identification of the occurrence, strength, and duration of ENSO extremes. Additionally, the duration-maximum anomaly excursion temperature association for ENSO extremes and the RP-duration association, previously found for EN events using ONI, were investigated to determine if they also might exist using the HadSST dataset, and the decadal aspects of the ENSO extremes were examined, anticipating what possibly might lie ahead for the current decade (2010–2019). Finally, table 7 is included in the Appendix, providing the monthly values of HadSST, 2-mma values of HadSST, 12-mma values of HadSST, the monthly differences between HadSST and the monthly adjusted average for 1871–2008 ($D(m)$), 2-mma values of $D(m)$ ($D(m2)$), ONI, SOI, SOI(2), and comments. The comments column notes the occurrences of ENSO extremes based on $D(m2)$, giving their start, peak, and end dates, as well as the strength of the individual peaks within each ENSO extreme event. For 1950–present, the occurrences of ENSO extremes are also shown based on ONI, marking their occurrences of start, peak, and end dates for comparison with $D(m2)$. The monthly adjusted averages of HadSST appear at the bottom of table 7.

This investigation has shown that the annual mean HadSST temperature for the Niño 3.4 region has averaged 26.95 °C between January 1871 and April 2009, with annual means varying nonrandomly, indicating the presence of a strong decadal signal imbedded within the dataset. Additionally, inferred was a possible rise over time of the annual mean SST temperature, but one of only marginal statistical importance (which disappears if one ignores the earliest portion of the data, prior to about 1895). Similar features are apparent in the annual highs, lows, and differences (i.e., high minus low values). Twelve-month moving averages of the nonseasonally adjusted monthly means of HadSST reveal strong episodic behavior, consisting of long intervals of warmer and cooler SST relative to the long-term mean. These episodes suggest the occurrences of long-term anomalous warming and cooling events. Instead, on the basis of 2-mma values of the seasonally adjusted monthly means of HadSST ($D(m2)$), one determines the occurrences of short-term episodes of warming and cooling, which are identified as EN and LN events, respectively (intervals of time when the anomalous monthly temperatures exceed specific thresholds continuously for a length of time longer than a specific minimum length).

For the interval February 1871–March 2009, the HadSST dataset is found to contain some 60 ENSO extreme events, consisting of 33 EN and 27 LN events. The duration of an ENSO extreme event is found to be associated with the strength of the event such that stronger events (those having larger anomalous temperature excursions) tend to persist longer than weaker events.

A comparison of D(m2) against SOI(2) and ONI during the ONI base period (1971–2000) reveals strong statistical correlation between D(m2) and both SOI(2) and, especially, ONI. The inferred correlation between D(m2) and SOI(2) has $r = -0.84$, meaning that the two descriptors of ENSO extreme events behave oppositely, warmer anomalous temperatures being associated with negative anomalous pressure differences, and cooler anomalous temperatures being associated with positive anomalous pressure differences. The inferred correlation between D(m2) and ONI is even stronger, having $r = 0.99$.

Comparison of the identification of EN and LN events using both the D(m2)- and ONI-determined listings for the interval 1950–2008 reveals subtle differences. For example, the very strong June 1973 LN (duration 13 months) and strong April 1975 LN (duration 12 months) events are identified as one long continuous strong LN event (with multiple peaks) in the ONI listing instead of two separate events. Other differences include the inclusion of a weak LN event of 5-months duration and a moderate EN event of 5-months duration in the D(m2) listing but neither appearing in the ONI listing of events, and the inclusion of a weak LN event of 5-months duration in the ONI listing but not appearing in the D(m2) listing of events. For the interval 1950–2008, ONI-determined extremes tend to be slightly longer in duration (about 1 month) than measured using D(m2).

For both D(m2)- and ONI-determined extremes, strong associations are inferred to exist between the duration of the events and their maximum anomalous excursion temperatures. Hence, based on D(m2), when max D(m2) was 1.38°C or warmer, the duration of the EN event was 10 months or longer (10–19 months, true for 17 of 17 EN events), and, when max D(m2) was -1.22°C or cooler, the duration of the LN event was 9 months or longer (9–31 months, true for 12 of 12 LN events). Similar results are found for ENSO extreme events based on ONI.

For both D(m2)- and ONI-determined ENSO extremes, a very strong association is inferred to exist between the occurrence of the next EN event and the duration of the last known EN event. For the interval 1950–2009, ONI-determined EN events tend to recur within 36 months when the duration of the last known EN event is less than 9 months, true for 6 of 8 EN events, while when the duration of the last known EN event is 10 months or longer, the recurrence rate tends to be 36 months or longer, true for 8 of 9 EN events. For the interval 1871–2008, D(m2)-determined EN events tend to recur within 37 months when the duration of the last known EN event is 10 months or less, true for 13 of 16 EN events, while when the duration of the last known EN event is 11 months or longer, the recurrence rate tends to be 41 months or longer, true for 13 of 16 EN events. Because the S 2009 EN event (recorded in the ONI-listing but not yet appearing in the HadSST dataset) has already persisted for 8 months (thru January 2010) and S EN events tend to persist 11–19 months (based on ONI, the shortest D(m2)-determined S EN persisted only 9 months, with 12 of 13 S EN events persisting 11–17 months), one should not expect another EN event to recur until June 2012 or later. (No such preferential association is found for LN events, either in the D(m2)- or ONI-determined listings.)

Finally, this study has shown that, since about the decade 1920–1929 the NENM have increased over time (in a saw-tooth pattern). Extrapolating the fit to the present decade (2010–2019), presuming the pattern to continue, one expects $\text{NENM} = 37 \pm 3$ months, probably ≥ 37 months (from the inferred saw-tooth pattern). This seems to indicate that one should expect about 3–4 EN events

during the present decade. For NLNM, the indication is that it decreased over time between the decades 1870–1879 and 1940–1949, but no preferential rise has since been seen. Instead, after two large increases during the decades 1950–1959 and 1970–1979, NLNM has steadily declined again from 44 months in the decade 1970–1979 to only 10 months in the last decade (2000–2009). It is unclear what the present decade will experience with regards to LN events. The median value for NLNM is 22.5 months per decade.

In conclusion, the D(m2) index, based on seasonally adjusted monthly HadSST values, can be used to describe ENSO conditions and identify ENSO extreme events. This study also confirms the existence of preferential behavior between the recurrence rate of EN events and the duration of the last known EN event, as well as, between the duration of an ENSO extreme event (both EN and LN events) and its maximum anomalous excursion temperature.

APPENDIX

Table 7 is included to provide monthly values of HadSST, 2-mma values of HadSST, 12-mma values of HadSST, the monthly differences between HadSST and the monthly adjusted average for 1871–2008 ($D(m)$), 2-mma values of $D(m)$ ($D(m2)$), ONI, SOI, SOI(2), and comments. The comments column notes the occurrences of ENSO extremes based on $D(m2)$, giving their start, peak, and end dates, as well as, the strength of the individual peaks. For 1950–present, the occurrences of ENSO extremes are also shown for ONI, marking the occurrences of the start, peak, and end dates, for comparison with $D(m2)$. The monthly-adjusted averages of HadSST appear at the bottom of table 7.

Table 7. SST monthly values of the Niño 3.4 region in degrees Celsius based on HadSST time series, ONI and SOI values, and the occurrences of EN (warm) and LN (cold) events from 1871 to the present.

Notes: HadSST = monthly values of the average temperature of the Niño 3.4 region, available at <http://www.cdc.noaa.gov/gcos_wgsp/Timeseries/Data/nino34.long.data>.

M = mean (1871–2008), M = 26.95.

sd = standard deviation (1871–2008), sd = 0.87.

CV = coefficient of variation (1871–2008), CV = sd/M = 0.032.

m = median (1871–2008), m = 26.96.

PCS = Pearson Coefficient of Skewness (1871–2008), PCS = 3(M–m)/sd = -0.034.

na = number of monthly values above median (1871–2008), na = 828.

nb = number of monthly values below median (1871–2008), nb = 828.

nra = number of runs above median (1871–2008), nra = 120.

z = the normal deviate of the monthly values (1871–2008), z = -28.94, a value indicating that the distribution of HadSST is highly nonrandom.

Table 7. SST monthly values of the Niño 3.4 region in degrees Celsius based on HadSST time series, ONI and SOI values, and the occurrences of EN (warm) and LN (cold) events from 1871 to the present (Continued).

2-mma = 2-month moving average.

12-mma = 12-month moving average.

D(m) = difference between HadSST and the monthly-adjusted average (1871–2008).

D(m2) = 2-mma of D(m).

ONI = Oceanic Niño Index based on ERSST.v3b, available at <http://www.cpc.noaa.gov/products/analysis_monitoring/ensostuff/ensoyears.shtml>.

* means SOI monthly values for 1871–1875 were taken from <http://www.cdc.noaa.gov/gcos_wgsp/Timeseries/Data/soi.long.data> and multiplied by 10; values from 1876–present were taken from <<http://www.bom.gov.au/climate/current/soihtml.shtml>>.

** means EN/LN determination based on D(m2).

EN means El Niño.

LN means La Niña.

M in comments column means moderate strength.

S means strong strength.

VS means very strong strength.

W means weak strength.

b means event start before, using ONI.

e means event end, using ONI.

p means event peak, using ONI.

s means event start, using ONI.

Monthly-adjusted averages of HadSST:

1871–2008

January	26.54

13. SUPPLEMENTARY NOTES Prepared by the Science and Exploration Vehicle Office, Science and Mission Systems Office					
14. ABSTRACT The Hadley sea-surface temperature (HadSST) dataset is investigated for the interval 1871–2008. The purpose of this investigation is to determine the degree of success in identifying and characterizing El Niño (EN) southern (ENSO) extreme events, both EN and La Niña (LN) events. Comparisons are made against both the Southern Oscillation Index for the same time interval and with published values of the Oceanic Niño Index for the interval since 1950. Some 60 ENSO extreme events are identified in the HadSST dataset, consisting of 33 EN and 27 LN events. Also, preferential associations are found to exist between the duration of ENSO extreme events and their maximum anomalous excursion temperatures and between the recurrence rate for an EN event and the duration of the last known EN event. Because the present ongoing EN is a strong event, it should persist 11 months or longer, inferring that the next EN event should not be expected until June 2012 or later. Furthermore, the decadal sum of EN-related months is found to have increased somewhat steadily since the decade of 1920–1929, suggesting that the present decade (2010–2019) possibly will see about 3–4 EN events, totaling about 37 ± 3 EN-related months (i.e., months that meet the definition for the occurrence of an EN event).					
15. SUBJECT TERMS Hadley sea-surface temperature, El Niño, La Niña, ENSO cycle, recurrence rates, ONI, SOI
